Lecture 11: Implementation Aspects

[IFAC PB Ch 12, RTCS Ch 11]

- 1. Sampling, aliasing, and choice of sampling interval
- 2. Computational delay
- 3. A-D and D-A quantization
- 4. Computer arithmetic
- 5. Controller realizations

Sampling and Aliasing

Recall this example from Lecture 6:

Aliasing

Sampling a signal with frequency $\boldsymbol{\omega}$ creates new signal components with frequencies

$$\omega_{\text{sampled}} = n\omega_s \pm \omega$$

where $\omega_s=2\pi/h$ is the sampling frequency and $n\in\mathbb{Z}$

Nyquist frequency:

$$\omega_N = \omega_s/2$$

The $\mathit{fundamental\ alias}\ \mathsf{for\ a\ signal\ with\ frequency\ }\omega$ is given by

$$\omega_{\text{fundamental}} = |(\omega + \omega_N) \mod (\omega_s) - \omega_N|$$

(This frequency lies in the interval $0 \le \omega_{\text{fundamental}} < \omega_N$)

Antialiasing Filter

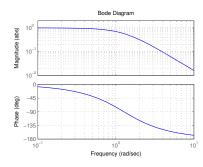

Low-pass filter that eliminates all frequencies above the Nyquist frequency before sampling. **Must contain analog part!** Options:

- · Analog filter
 - E.g. 2-6th order Bessel or Butterworth filter
 - Difficult to change sampling interval
- Analog + digital filter
 - Fixed, fast sampling with fixed analog filter
 - Downsampling using digital LP-filter
 - Control algorithm at the lower rate
 - Easier to change sampling interval

Example: Second-Order Bessel Filter

$$G_f(s) = \frac{\omega^2}{(s/\omega_B)^2 + 2\zeta\omega(s/\omega_B) + \omega^2}, \quad \omega = 1.27, \; \zeta = 0.87$$

 $\omega_B = 1$:

Antialiasing Filter and Control Design

As a rule of thumb, the cut-off frequency of the filter should be chosen so that

$$|G_f(i\omega_N)| \leq 0.1$$
,

meaning that frequencies above the Nyquist frequency are attenuated by at least a factor 10.

Unless extremely fast sampling is used, the filter will affect the phase margin of the system. Include the filter in the process description or approximate it by a delay.

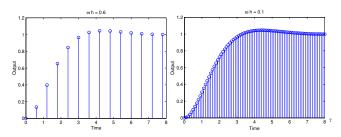

- Digital design: E.g. 2nd order Bessel filter: $\tau\approx 1.3/\omega_B$. If $|G_f(i\omega_N)|=0.1$ then $\tau\approx 1.5h$
- Analog design + discretization: must sample fast

Choice of Sampling Interval - Digital Design

Common rule of thumb:

$$\omega h \approx 0.1$$
 to 0.6

 ω is the desired natural frequency of the closed-loop system Gives about 4 to 20 samples per rise time

Choice of Sampling Interval - Analog Design

Sampler + ZOH pprox delay of $0.5h \Leftrightarrow e^{-s0.5h}$

Antialiasing filter \approx delay of $1.5h \Leftrightarrow e^{-s1.5h}$

Will affect phase margin (at cross-over frequency ω_c) by

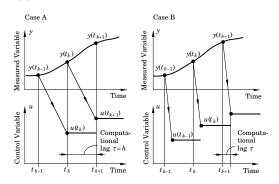

$$\arg e^{-i\omega_c 2h} = -2\omega_c h$$

Assume phase margin can be decreased by 5° to 15° (= 0.087 to 0.262 rad). Then

$$\omega_c h \approx 0.04$$
 to 0.13

Computational delay

Problem: u(k) cannot be generated instantaneously at time k when y(k) is sampled. Options:

Minimizing the computational delay

A general linear controller in state-space form (including state feedback, observer, reference model, etc.):

$$x_c(k+1) = Fx_c(k) + Gy(k) + G_cu_c(k)$$

 $u(k) = Cx_c(k) + Dy(k) + D_cu_c(k)$

Do as little as possible between the input and the output:

Finite-Wordlength Implementation

Control analysis and design usually assumes infinite-precision arithmetic, parameters/variables are assumed to be real numbers

Error sources in a digital implementation with finite wordlength:

- · Quantization in A-D converters
- Quantization of parameters (controller coefficients)
- Round-off and overflow in addition, subtraction, multiplication, division, function evaluation and other operations
- · Quantization in D-A converters

The magnitude of the problems depends on

- The wordlength
- The type of arithmetic used (fixed or floating point)
- The controller realization

11

A-D and D-A Quantization

A-D and D-A converters often have quite poor resolution, e.g.

• A-D: 10-16 bits

• D-A: 8-12 bits

Quantization is a nonlinear phenomenon; can lead to limit cycles and bias. Analysis approaches (outside scope of this course):

· Nonlinear analysis

- Describing function approximation

- Theory of relay oscillations

· Linear analysis

- Quantization as a stochastic disturbance

Example: Control of the Double Integrator

Process:

$$P(s) = 1/s^2$$

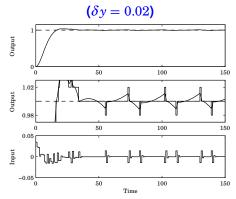

Sampling period:

$$h = 1$$

Controller (PID):

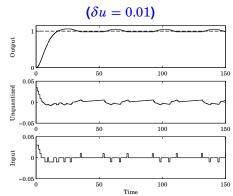

$$C(z) = \frac{0.715z^2 - 1.281z + 0.580}{(z - 1)(z + 0.188)}$$

Simulation with Quantized A-D Converter

Limit cycle in process output with period 28 s, ampl. 0.01

Simulation with Quantized D-A Converter

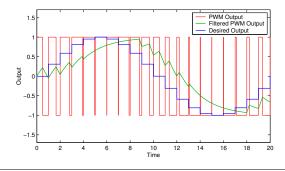

Limit cycle in process input with period 39 s, ampl. 0.01

Pulse-Width Modulation (PWM)

Poor D-A resolution (e.g. 1 bit) can often be handled by fast switching between levels + low-pass filtering

The new control variable is the duty-cycle of the switched signal

Floating-Point Arithmetic

Hardware-supported on modern high-end processors (FPUs) Number representation:

$$\pm f \times 2^{\pm e}$$

• *f*: mantissa, significand, fraction

2: base

• e: exponent

The binary point is variable (floating) and depends on the value of the exponent

Dynamic range and resolution

Fixed number of significant digits

14

16

IEEE 754 Binary Floating-Point Standard

Used by almost all FPUs; implemented in software libraries

Single precision (Java/C float):

- 32-bit word divided into 1 sign bit, 8-bit biased exponent, and 23-bit mantissa (≈ 7 decimal digits)
- Range: $2^{-126} 2^{128}$

Double precision (Java/C double):

- 64-bit word divided into 1 sign bit, 11-bit biased exponent, and 52-bit mantissa (≈ 15 decimal digits)
- Range: $2^{-1022} 2^{1024}$

Supports Inf and NaN

19

21

What is the output of this C program?

```
#include <stdio.h>
main() {

   float a[] = { 10000.0, 1.0, 10000.0 };
   float b[] = { 10000.0, 1.0, -10000.0 };
   float sum = 0.0;
   int i;

   for (i=0; i<3; i++)
      sum += a[i]*b[i];

   printf("sum = %f\n", sum);
}</pre>
```

20

Remarks:

- The result depends on the order of the operations
- Finite-wordlength operations are neither associative nor distributive

Arithmetic in Embedded Systems

Small microprocessors used in embedded systems typically do not have hardware support for floating-point arithmetic

Options:

- Software emulation of floating-point arithmetic
 - compiler/library supported
 - large code size, slow
- Fixed-point arithmetic
 - often manual implementation
 - fast and compact

22

Fixed-Point Arithmetic

Represent all numbers (parameters, variables) using integers

Use **binary scaling** to make all numbers fit into one of the integer data types, e.g.

- 8 bits (char, int8_t): [-128, 127]
- 16 bits (short, int16_t): [-32768, 32767]
- 32 bits (long, int32_t): [-2147483648, 2147483647]

Challenges

- Must select data types to get sufficient numerical precision
- Must know (or estimate) the minimum and maximum value of every variable in order to select appropriate scaling factors
- Must keep track of the scaling factors in all arithmetic operations
- Must handle potential arithmetic overflows

1

Fixed-Point Representation

In fixed-point representation, a real number x is represented by an integer X with N=m+n+1 bits, where

- N is the wordlength
- *m* is the number of integer bits (excluding the sign bit)
- *n* is the number of fractional bits

"Q-format": X is sometimes called a Qm.n or Qn number

Conversion to and from fixed point

Conversion from real to fixed-point number:

$$X := \text{round}(x \cdot 2^n)$$

Conversion from fixed-point to real number:

$$x := X \cdot 2^{-n}$$

Example: Represent x = 13.4 using Q4.3 format

$$X = \text{round}(13.4 \cdot 2^3) = 107 \ (= 01101011_2)$$

A Note on Negative Numbers

In almost all CPUs today, negative integers are handled using **two's complement**: A "1" in the sign bit means that 2^N should be subtracted from the stored value

Example (N = 8):

Binary representation	Interpretation	
00000000	0	
0000001	1	
:	:	
01111111	127	
10000000	-128	
10000001	-127	
:	÷	
1111111	-1	

Range vs Resolution for Fixed-Point Numbers

A Qm.n fixed-point number can represent real numbers in the range

$$[-2^m, 2^m - 2^{-n}]$$

while the resolution is

 2^{-n}

Fixed range and resolution

- n too small \Rightarrow poor resolution
- n too large \Rightarrow risk of overflow

Example: Choose number of integer and fractional bits

We want to store x in a signed 8-bit variable.

We know that -28.3 < x < 17.5.

We hence need m=5 bits to represent the integer part. $(2^4=16<28.3<32=2^5)$

n = 8 - 1 - m = 2 bits are left for the fractional part.

 \boldsymbol{x} should be stored in Q5.2 format

Fixed-Point Addition/Subtraction

Two fixed-point numbers in the same Qm.n format can be added or subtracted directly

The result will have the same number of fractional bits

$$z = x + y \Leftrightarrow Z = X + Y$$

$$z = x - y \quad \Leftrightarrow \quad Z = X - Y$$

ullet The result will in general require N+1 bits; risk of overflow

29

Example: Addition with Overflow

Two numbers in Q4.3 format are added:

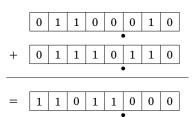

$$x = 12.25 \quad \Rightarrow \quad X = 98$$

$$y = 14.75 \Rightarrow Y = 118$$

$$Z = X + Y = 216$$

This number is however out of range and will be interpreted as

$$216 - 256 = -40 \implies z = -5.0$$

Fixed-Point Multiplication and Division

If the operands and the result are in the same Q-format, multiplication and division are done as

$$z = x \cdot y \quad \Leftrightarrow \quad Z = (X \cdot Y)/2^n$$

$$z = x/y \Leftrightarrow Z = (X \cdot 2^n)/Y$$

- Double wordlength is needed for the intermediate result
- ullet Division by 2^n is implemented as a right-shift by n bits
- ullet Multiplication by 2^n is implemented as a left-shift by n bits
- The lowest bits in the result are truncated (round-off noise)
- Risk of overflow

Example: Multiplication

Two numbers in Q5.2 format are multiplied:

$$x = 6.25 \Rightarrow X = 25$$

$$y = 4.75 \Rightarrow Y = 19$$

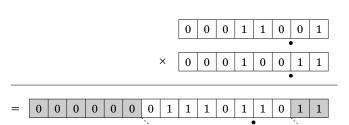

Intermediate result:

$$X \cdot Y = 475$$

Final result:

$$Z = 475/2^2 = 118 \implies z = 29.5$$

(exact result is 29.6875)

Example: Division

Two numbers in Q3.4 format are divided:

$$x = 5.375$$
 \Rightarrow $X = 86$
 $y = 6.0625$ \Rightarrow $Y = 97$

Not associative:

$$Z_{bad} = (X/Y) \cdot 2^4 = (86/97) \cdot 2^4 = 0 \cdot 2^4 = 0$$

$$Z_{good} = (X \cdot 2^4)/Y = 1376/97 = 14 \implies z = 0.875$$

(correct first 6 digits are 0.888531)

35

31

Multiplication of Operands with Different Q-format

In general, multiplication of two fixed-point numbers $Qm_1.n_1$ and $Qm_2.n_2$ gives an intermediate result in the format

$$Qm_1+m_2.n_1+n_2$$

which may then be right-shifted $n_1 + n_2 - n_3$ steps and stored in the format

 $Qm_3.n_3$

Common case: $n_2=n_3=0$ (one real operand, one integer operand, and integer result). Then

$$Z = (X \cdot Y)/2^{n_1}$$

•

Implementation of Multiplication in C

Assume Q4.3 operands and result

38

Implementation of Multiplication in C with Rounding and Saturation

```
/* defines int8_t, etc. (Linux only)
#include <inttypes.h>
#define n 3
                          /* number of fractional bits
                          /* Q4.3 operands and result
int8 t X, Y, Z;
                          /* Q9.6 intermediate result
int16_t temp;
                          /* cast operands to 16 bits and multiply */
temp = (int16_t)X * Y;
temp = temp + (1 << n-1); /* add 1/2 to give correct rounding
temp = temp >> n;
                          /* divide by 2^n
if (temp > INT8_MAX)
                          /* saturate the result before assignment */
  Z = INT8_MAX;
else if (temp < INT8_MIN)
  Z = INT8_MIN;
else
  Z = temp;
```

39

37

Implementation of Division in C with Rounding

```
#include <inttypes.h>
                          /* define int8_t, etc. (Linux only)
#define n 3
                          /* number of fractional bits
int8_t X, Y, Z;
                         /* Q4.3 operands and result
int16_t temp;
                         /* Q9.6 intermediate result
                         /* cast operand to 16 bits and shift
temp = (int16_t)X << n;
temp = temp + (Y >> 1);
                         /* Add Y/2 to give correct rounding
temp = temp / Y;
                         /* Perform the division (expensive!)
Z = temp;
                         /* Truncate and assign result
```

40

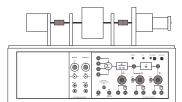

Atmel mega8/16 instruction set

Mnemonic	Description	# clock cycles
ADD	Add two registers	1
SUB	Subtract two registers	1
MULS	Multiply signed	2
ASR	Arithmetic shift right (1 step)	1
LSL	Logical shift left (1 step)	1

 No division instruction; implemented in math library using expensive division algorithm

Laboratory Exercise 3

· Control of a rotating DC servo using the ATmega16

- Velocity control (PI controller)
- Position control (state feedback from extended observer)
- Floating-point and fixed-point implementations
- Measurement of code size and execution time

42

Example Evaluation: Measurements

Floating-point implementation using floats:

Velocity control: 950 μs
Position control: 1220 μs
Total code size: 13708 bytes

Fixed-point implementation using 16-bit integers:

Velocity control: 130 μs
Position control: 270 μs
Total code size: 3748 bytes

The measured times include 115 μ s A-D conversion. This gives a 25–50 times actual speedup for fixed point math compared to floating point. The floating point math library takes about 10K (out of 16K available!)

Controller Realizations

A linear controller

$$H(z) = \frac{b_0 + b_1 z^{-1} + \ldots + b_n z^{-n}}{1 + a_1 z^{-1} + \ldots + a_n z^{-n}}$$

can be realized in a number of different ways with equivalent input-output behavior, e.g.

- Direct form
- · Companion (canonical) form
- Series (cascade) or parallel form

Direct Form

The input-output form can be directly implemented as

$$u(k) = \sum_{i=0}^{n} b_i y(k-i) - \sum_{i=1}^{n} a_i u(k-i)$$

- Nonminimal (all old inputs and outputs are used as states)
- Very sensitive to roundoff in coefficients
- Avoid!

Companion Forms

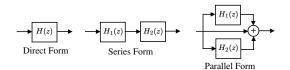

E.g. controllable or observable canonical form

$$x(k+1) = \begin{pmatrix} -a_1 & -a_2 & \cdots & -a_{n-1} & -a_n \\ 1 & 0 & & 0 & 0 \\ 0 & 1 & & 0 & 0 \\ \vdots & & & & & \\ 0 & 0 & & 1 & 0 \end{pmatrix} x(k) + \begin{pmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix} y(k)$$
$$u(k) = \begin{pmatrix} b_1 & b_2 & \cdots & b_n \end{pmatrix} x(k)$$

- · Same problem as for the Direct form
- · Very sensitive to roundoff in coefficients
- Avoid!

Better: Series and Parallel Forms

Divide the transfer function of the controller into a number of first- or second-order subsystems:

• Try to balance the gain such that each subsystem has about the same amplification

Example: Series and Parallel Forms

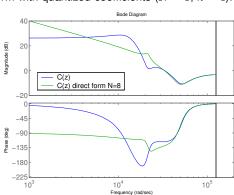

$$C(z) = \frac{z^4 - 2.13z^3 + 2.351z^2 - 1.493z + 0.5776}{z^4 - 3.2z^3 + 3.997z^2 - 2.301z + 0.5184}$$
(Direct)

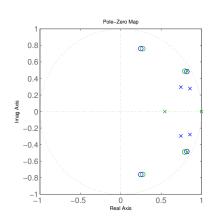

$$= \left(\frac{z^2 - 1.635z + 0.9025}{z^2 - 1.712z + 0.81}\right) \left(\frac{z^2 - 0.4944z + 0.64}{z^2 - 1.488z + 0.64}\right)$$
 (Series)

$$=1+\frac{-5.396z+6.302}{z^2-1.712z+0.81}+\frac{6.466z-4.907}{z^2-1.488z+0.64} \qquad \text{(Parallel)}$$

7

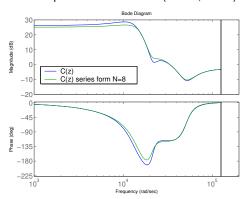

Direct form with quantized coefficients (N = 8, n = 4):

50

Series form with quantized coefficients (N=8, n=4):

Jackson's Rules for Series Realizations

Short Sampling Interval Modification

How to pair and order the poles and zeros?

Jackson's rules (1970):

- Pair the pole closest to the unit circle with its closest zero.
 Repeat until all poles and zeros are taken.
- Order the filters in increasing or decreasing order based on the poles closeness to the unit circle.

This will push down high internal resonance peaks.

In the state update equation

$$x(k+1) = \Phi x(k) + \Gamma y(k)$$

the system matrix Φ will be close to I if h is small. Round-off errors in the coefficients of Φ can have drastic effects.

Better: use the modified equation

$$x(k+1) = x(k) + (\Phi - I)x(k) + \Gamma y(k)$$

- \bullet Both $\Phi-I$ and Γ are roughly proportional to h
 - Less round-off noise in the calculations
- ullet Also known as the δ -form

Short Sampling Interval and Integral Action

Fast sampling and slow integral action can give roundoff problems:

$$I(k+1) = I(k) + \underbrace{e(k) \cdot h/T_i}_{\approx 0}$$

Possible solutions:

- Use a dedicated high-resolution variable (e.g. 32 bits) for the I-part
- Update the I-part at a slower rate

(This is a general problem for filters with very different time constants)
