Lecture 10 — Optimal Control

- Introduction
- Static Optimization with Constraints
- Optimization with Dynamic Constraints
- The Maximum Principle
- Examples

Material

- Lecture slides
- References to Glad & Ljung, part of Chapter 18 Note: page references to Swedish edition

Goal

To be able to

- solve simple optimal control problems by hand
- design controllers

using the maximum principle

Optimal Control Problems

Idea: Formulate the design problem as optimization problem

- + Gives systematic design procedure
- + Can use on nonlinear models
- + Can capture limitations etc as constraints
- Hard to find suitable criterium?!
- Can be hard to find the optimal controller

Solutions will often be of "bang-bang" character if control signal is bounded, compare lecture on sliding mode controllers.

The beginning

John Bernoulli: The bracistochrone problem 1696
 Let a particle slide along a frictionless curve. Find the curve that takes the particle from A to B in shortest time

Solved by John and James Bernoulli, Newton, l'Hospital
 Euler: Isoperimetric problems

 Example: The largest area covered by a curve of given

$$J(y) = \int_0^1 \frac{\sqrt{1 + y'(x)^2}}{\sqrt{2gy(x)}} \, dx$$

- Solved by John and James Bernoulli, Newton, l'Hospital
- Euler: Isoperimetric problems
 - Example: The largest area covered by a curve of given length is a circle [see also Dido/cow-skin/Carthage].

Optimal Control

- The space race (Sputnik 1957)
- Putting satellites in orbit
- Trajectory planning for interplanetary travel
- Reentry into atmosphere
- Minimum time problems
- Pontryagin's maximum principle, 1956
- Dynamic programming, Bellman 1957
- Vitalization of a classical field

An example: Goddard's Rocket Problem (1910)

How to send a rocket as high up in the air as possible?

$$\frac{d}{dt} \begin{pmatrix} v \\ h \\ m \end{pmatrix} = \begin{pmatrix} \frac{u-D}{m} - g \\ v \\ -\gamma u \end{pmatrix} \qquad \qquad h$$

where u = motor force, D(v, h) = air resistance, m = mass.

Constraints

$$0 \le u \le u_{max}, \quad m(t_f) \ge m_1$$

Criterium

Maximize
$$h(t_f)$$
, t_f given

Goddard's Problem

Can you guess the solution when D(v, h) = 0?

Much harder when $D(v,h) \neq 0$

Can be optimal to have low v when air resistance is high. Burn fuel at higher level.

Took about 50 years before a complete solution was found.

Read more about Goddard at http://www.nasa.gov/centers/goddard/

Optimal Control Problem. Constituents

```
Control signal u(t), 0 \le t \le t_f
Criterium h(t_f).
Differential equations relating h(t_f) and u
Constraints on u
Constraints on x(0) and x(t_f)
t_f can be fixed or a free variable
```

Outline

- Introduction
- Static Optimization with Constraints
- Optimization with Dynamic Constraints
- The Maximum Principle
- Examples

Preliminary: Static Optimization

Minimize $g_1(x, u)$ over $x \in \mathbb{R}^n$ and $u \in \mathbb{R}^m$ s.t. $g_2(x, u) = 0$ (Assume $g_2(x, u) = 0 \Rightarrow \partial g_2(x, u) / \partial x$ non-singular)

Lagrangian:
$$\mathcal{L}(x, u, \lambda) = g_1(x, u) + \lambda^T g_2(x, u)$$

Local minima of $g_1(x, u)$ constrained on $g_2(x, u) = 0$ can be mapped into critical points of $\mathcal{L}(x, u, \lambda)$

Necessary conditions for local minimum

$$rac{\partial \mathcal{L}}{\partial x} = 0 \qquad rac{\partial \mathcal{L}}{\partial u} = 0 \qquad \left(rac{\partial \mathcal{L}}{\partial \lambda} = g_2(x, u) = 0
ight)$$

Note: Difference if constrained control!

Example - static optimization

Minimize

$$g_1(x_1, x_2) = x_1^2 + x_2^2$$

with the constraint that

$$g_2(x_1, x_2) = x_1 \cdot x_2 - 1 = 0$$

Level curves for constant g_1 and the constraint $g_2 = 0$, repectively.

Static Optimization cont'd

Solving the equations

$$\frac{\partial \mathcal{L}}{\partial x} = \frac{\partial g_1}{\partial x} + \lambda^T \frac{\partial g_2}{\partial x} = 0 \Rightarrow \lambda^T = -\frac{\partial g_1}{\partial x} \left(\frac{\partial g_2}{\partial x}\right)^{-1}$$
$$\frac{\partial \mathcal{L}}{\partial u} = \frac{\partial g_1}{\partial u} + \lambda^T \frac{\partial g_2}{\partial u} = 0 \Rightarrow \frac{\partial g_1}{\partial u} - \frac{\partial g_1}{\partial x} \left(\frac{\partial g_2}{\partial x}\right)^{-1} \frac{\partial g_2}{\partial u} = 0$$

This gives m equations to solve for u.

Sufficient condition for local minimum

$$\frac{\partial^2 \mathcal{L}}{\partial u^2} > 0$$

Optimization with Dynamic Constraint

Optimal Control Problem

$$\min_{u} J = \min_{u} \left\{ \phi(x(t_f)) + \int_{t_0}^{t_f} L(x, u) \, dt \right\}$$

subject to

$$\dot{x} = f(x, u), \quad x(t_0) = x_0$$

Introduce Hamiltonian: $H(x, u, \lambda) = L(x, u) + \lambda^T f(x, u)$

$$egin{aligned} J &= \phi(x(t_f)) + \int_{t_0}^{t_f} \left(L(x,u) + \lambda^T(f-\dot{x})
ight) \, dt \ &= \phi(x(t_f)) - \left[\lambda^T x
ight]_{t_0}^{t_f} + \int_{t_0}^{t_f} \left(H + \dot{\lambda}^T x
ight) \, dt \end{aligned}$$

second equality obtained from "integration by parts".

Optimization with Dynamic Constraint cont'd

Variation of J:

$$\delta J = \left[\left(\frac{\partial \phi}{\partial x} - \lambda^T \right) \delta x \right]_{t=t_f} + \int_{t_0}^{t_f} \left[\left(\frac{\partial H}{\partial x} + \dot{\lambda}^T \right) \delta x + \frac{\partial H}{\partial u} \delta u \right] dt$$

Necessary conditions for local minimum ($\delta J = 0$)

$$\lambda(t_f)^T = \left. \frac{\partial \phi}{\partial x} \right|_{t=t_f} \qquad \dot{\lambda}^T = -\frac{\partial H}{\partial x} \qquad \left. \frac{\partial H}{\partial u} = 0 \right.$$

- Adjoined, or co-state, variables, $\lambda(t)$
- λ specified at $t = t_f$ and x at $t = t_0$
- Two Point Boundary Value Problem (TPBV)

• For sufficiency
$$\frac{\partial^2 H}{\partial u^2} \ge 0$$

Outline

- Introduction
- Static Optimization with Constraints
- Optimization with Dynamic Constraints
- The Maximum Principle
- Examples

Problem Formulation (1)

Standard form (1):

$$\begin{array}{l} \text{Minimize} \quad \int_{0}^{t_{f}} \overbrace{L(x(t),u(t))}^{\text{Trajectory cost}} dt + \overbrace{\phi(x(t_{f}))}^{\text{Final cost}} \\ \dot{x}(t) = f(x(t),u(t)) \\ u(t) \in U, \quad 0 \leq t \leq t_{f}, \quad t_{f} \text{ given} \\ x(0) = x_{0} \end{array}$$

 $x(t) \in \mathbb{R}^n, u(t) \in \mathbb{R}^m$

 $U \subseteq R^m$ control constraints

Here we have a fixed end-time t_f . This will be relaxed later on.

The Maximum Principle (18.2)

Introduce the Hamiltonian

$$H(x, u, \lambda) = L(x, u) + \lambda^{T}(t) f(x, u).$$

Assume optimization (1) has a solution $\{u^*(t), x^*(t)\}$. Then

$$\min_{u\in U}H(x^*(t),u,\lambda(t))=H(x^*(t),u^*(t),\lambda(t)),\quad 0\leq t\leq t_f,$$

where $\lambda(t)$ solves the **adjoint equation**

$$d\lambda(t)/dt = -H_x^T(x^*(t), u^*(t), \lambda(t)), \quad \text{with} \quad \lambda(t_f) = \phi_x^T(x^*(t_f))$$

Notation

$$H_x = \frac{\partial H}{\partial x} = \begin{pmatrix} \frac{\partial H}{\partial x_1} & \frac{\partial H}{\partial x_2} \dots \end{pmatrix}$$

Remarks

Proof: If you are theoretically interested look in [Glad & Ljung].

Idea: note that every change of u(t) from the suggested optimal $u^*(t)$ must lead to larger value of the criterium.

Should be called "minimum principle"

 $\lambda(t)$ are called the Lagrange multipliers or the adjoint variables

Remarks

The Maximum Principle gives necessary conditions

A pair $(u^*(\cdot), x^*(\cdot))$ is called **extremal** the conditions of the Maximum Principle are satisfied. Many extremals can exist.

The maximum principle gives all possible candidates.

However, there might not exist a minimum!

Example

Minimize x(1) when $\dot{x}(t) = u(t)$, x(0) = 0 and u(t) is free

Why doesn't there exist a minimum?

Outline

- Introduction
- Static Optimization with Constraints
- Optimization with Dynamic Constraints
- The Maximum Principle
- Examples

Example–Boat in Stream

Speed of water $v(x_2)$ in x_1 direction. Move maximum distance in x_1 -direction in fixed time T

Assume *v* linear so that $v'(x_2) = 1$

Solution

Hamiltonian:

$$H = 0 + \lambda^T f = \begin{bmatrix} \lambda_1 & \lambda_2 \end{bmatrix} \begin{bmatrix} f_1 \\ f_2 \end{bmatrix} = \lambda_1 (v(x_2) + u_1) + \lambda_2 u_2$$

Adjoint equation:

$$\begin{bmatrix} \dot{\lambda}_1 \\ \dot{\lambda}_2 \end{bmatrix} = \begin{bmatrix} -\partial H / \partial x_1 \\ -\partial H / \partial x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ -v'(x_2)\lambda_1 \end{bmatrix} = \begin{bmatrix} 0 \\ -\lambda_1 \end{bmatrix}$$

with boundary conditions

$$egin{bmatrix} \lambda_1(T)\ \lambda_2(T) \end{bmatrix} = egin{bmatrix} \partial \phi / \partial x_1 |_{x=x^*(t_f)}\ \partial \phi / \partial x_2 |_{x=x^*(t_f)} \end{bmatrix} = egin{bmatrix} -1\ 0 \end{bmatrix}$$

This gives $\lambda_1(t) = -1$, $\lambda_2(t) = t - T$

Solution

Optimality: Control signal should solve

$$\min_{u_1^2+u_2^2=1}\lambda_1(v(x_2)+u_1)+\lambda_2u_2$$

Minimize $\lambda_1 u_1 + \lambda_2 u_2$ so that (u_1, u_2) has length 1

$$u_1(t) = -\frac{\lambda_1(t)}{\sqrt{\lambda_1^2(t) + \lambda_2^2(t)}}, \quad u_2(t) = -\frac{\lambda_2(t)}{\sqrt{\lambda_1^2(t) + \lambda_2^2(t)}}$$
$$u_1(t) = \frac{1}{\sqrt{1 + (t - T)^2}}, \quad u_2(t) = \frac{T - t}{\sqrt{1 + (t - T)^2}}$$

See fig 18.1 for plots

Remark: It can be shown that this optimal control problem has a minimum. Hence it must be the one we found, since this was the only solution to MP

5 min exercise

Solve the optimal control problem

$$\min \int_0^1 u^4 dt + x(1)$$
$$\dot{x} = -x + u$$
$$x(0) = 0$$

5 min exercise - solution

Compare with standard formulation:

$$t_f = 1$$
 $L = u^4$ $\phi = x$ $f(x) = -x + u$

Need to introduce one adjoint state

Hamiltonian:

$$H = L + \lambda^T \cdot f = u^4 + \lambda(-x + u)$$

Adjoint equation:

$$\frac{d\lambda}{dt} = -\frac{\partial H}{\partial x} = -(-\lambda) \implies \lambda(t) = Ce^{t}$$
$$\lambda(t_{f}) = \frac{\partial \phi}{\partial x} = 1 \implies \lambda(t) = e^{t-1}$$

At optimality:

$$0 = \frac{\partial H}{\partial u} = 4u^3 + \lambda$$
$$\implies u(t) = \sqrt[3]{-\lambda(t)/4} = \sqrt[3]{-e^{(t-1)}/4}$$

Goddard's Rocket Problem revisited

How to send a rocket as high up in the air as possible?

$$\frac{d}{dt} \begin{pmatrix} v \\ h \\ m \end{pmatrix} = \begin{pmatrix} \frac{u-D}{m} - g \\ v \\ -\gamma u \end{pmatrix} \qquad \qquad h$$

 $(v(0), h(0), m(0)) = (0, 0, m_0), g, \gamma > 0$ u motor force, D = D(v, h) air resistance

Constraints: $0 \le u \le u_{max}$ and $m(t_f) = m_1$ (empty)

Optimization criterion: $\max_{t_f, u} h(t_f)$

Problem Formulation (2)

$$\min_{\substack{t_f \ge 0 \\ u:[0,t_f] \to U}} \int_0^{t_f} L(x(t), u(t)) \, dt + \phi(t_f, x(t_f)) \\ \dot{x}(t) = f(x(t), u(t)), \quad x(0) = x_0 \\ \psi(t_f, x(t_f)) = 0$$

Note the differences compared to standard form:

t_f free variable (i.e., not specified *a priori*)
 r end constraints

$$\Psi(t_f, x(t_f)) = \begin{pmatrix} \Psi_1(t_f, x(t_f)) \\ \vdots \\ \Psi_r(t_f, x(t_f)) \end{pmatrix} = 0$$

• time varying final penalty, $\phi(t_f, x(t_f))$

The Maximum Principle will be generalized in the next lecture!
